Introduction

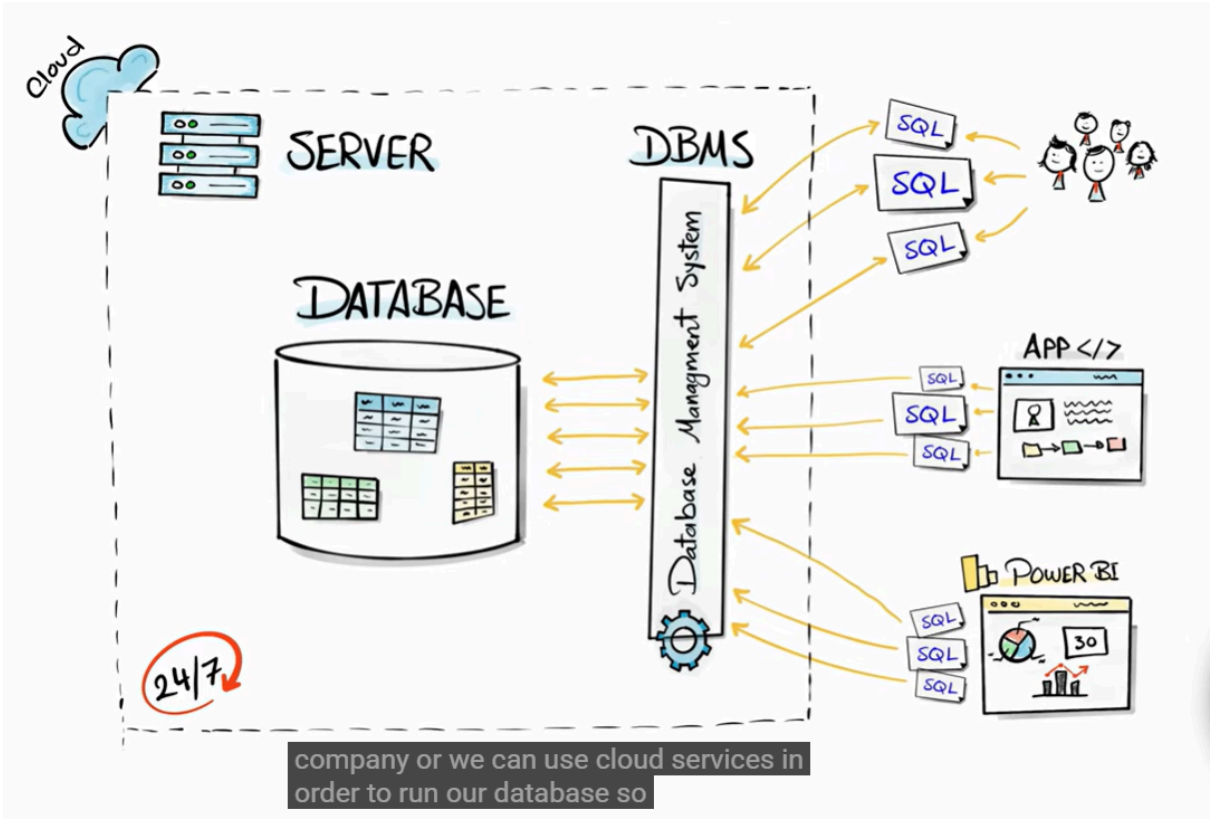

1. What is SQL

1. SQL → Structured Query Language
2. A company or any organization have the data int it like employees data/company data
3. Server has the DataBase to store the data of that particular organization → we can say it as the hardware drive like , where server has the database
4. in that database we have our data in different forms
    a. example in MySql/Postgre Sql → have the data in the form of tables
    b. MongoDb have the data in the form of documents
5. And to access any data from the database(that contains data) we need a language where Sql helps us to do that
6. Sql helps to retrive the data from database tables

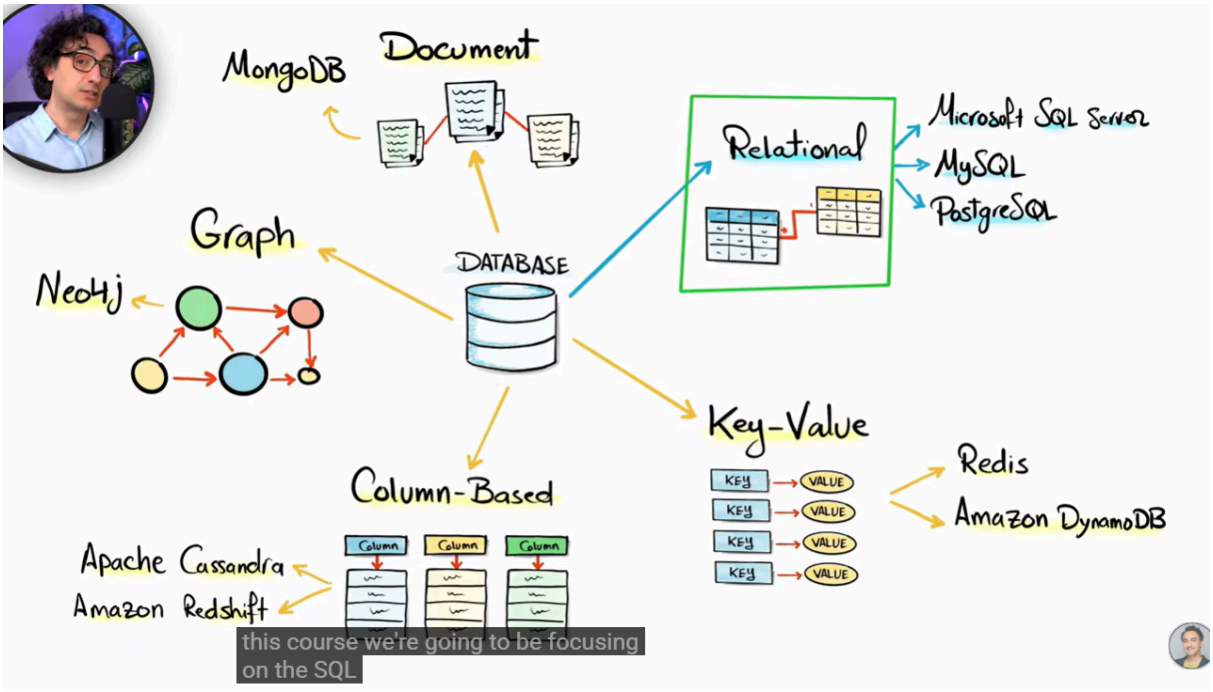

7. That DataBase is managed by the DBMS → to avoid conflicts caused by multiple requests and protect the data

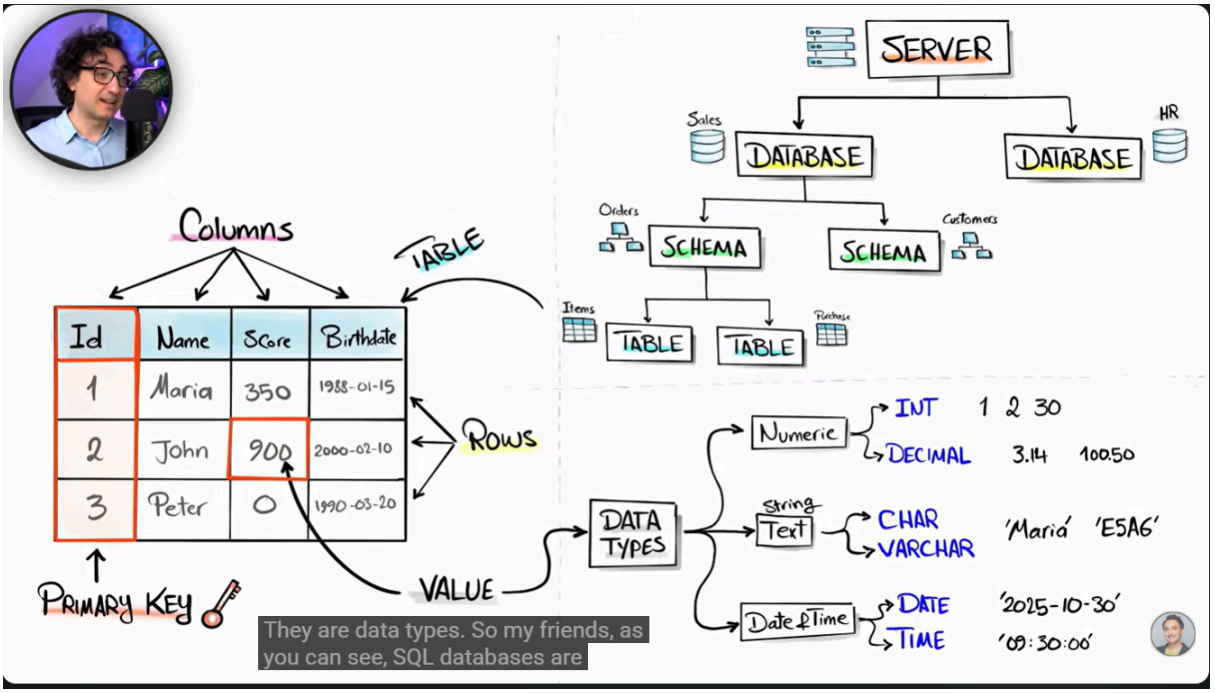

8. Sql queries and all are like software . hardware → DataBase , we need a server to store that data and that need to be active always , else requests get failed → do cloud helps us so that our server is active always

- Finally Database → Stores data
- SQL → Speak to Database
- DBMS → Manages Database
- Server → Where DataBase lives

DataBase and its Types

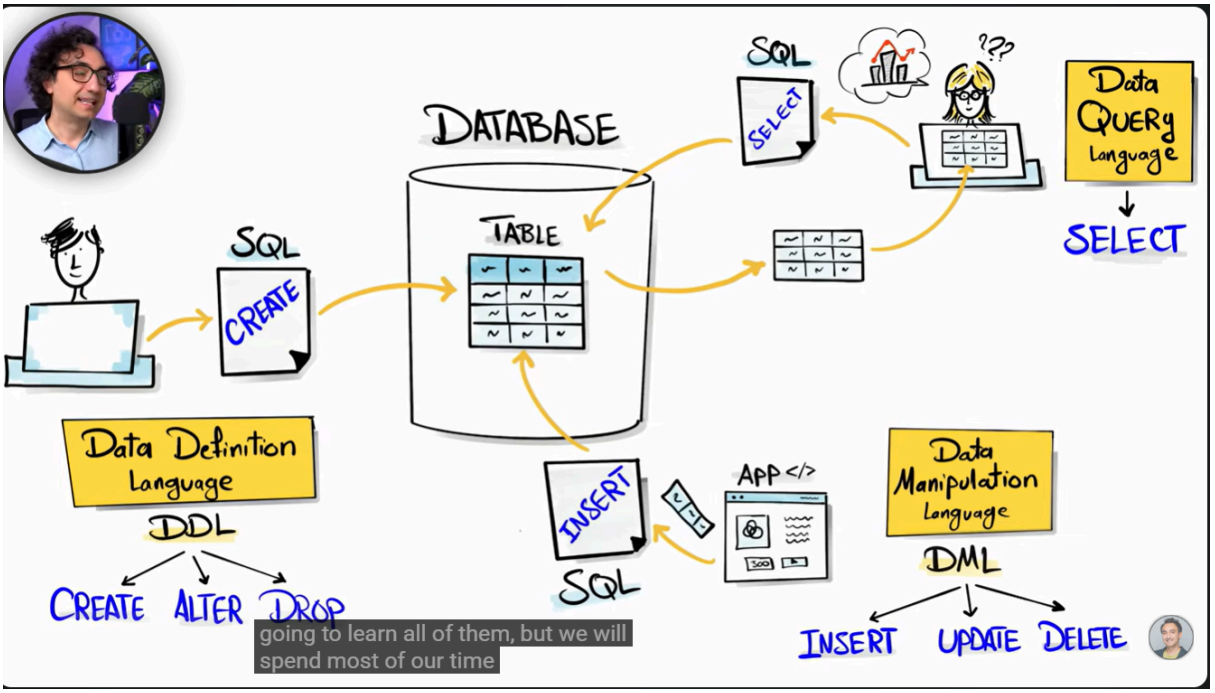

1. All are NoSql excpet the Relational database which is SQL

1. In Schema only we define the datatypes of respective variables we use to create tables
2. Schema is fixed , which cannot be changed . but Table and its values are changable
3. Schema describes the structure of the Table → what columns needed to be there,what datatype needed to be. Tells the Primarykey and all other related to tables

SQL Commands

DDl → for Tables

DML → to manipulate data in Tables

SQL → to retrieve data from table

1. In SQL → columns are called as ⇒ Fields/Attributes
2. Rows → called as Records
